

Week 4: Advanced Session on Optimization

- ◆ How to transform a poorly behaved non-linear formulation
 - Into a well-behaved linear formulation
- ◆ Reminder: this is an optional session for the curious
 - You won't be tested on this material
- ◆ Agenda
 - Remember IDEA's optimization problem from Session 3
 - Look at the algebraic formulation
 - Graph the "min" statement that calculates revenues and see that is not linear
 - Use the graph to show how to modify the formulation to make it linear
 - Update the algebraic formulation to make it linear
 - Implement the linear optimization problem in Excel

Recall IDEA chooses an order quantity Q for Supplier P

- ◆ Demand forecast...for example, if the market were strong
 - Uniformly distributed from 6,000 to 14,000 units
- ◆ Revenues and costs for supplier P
 - Sales price = 150€
 - Unit cost = 100€
 - Fixed cost to contract with P = 100,000€
- ◆ If IDEA were to order Q and demand turned out to be D...
 - Earn $150€ \cdot \min\{D, Q\}$ in sales revenue
 - Pay $100€ \cdot Q$ in unit costs
 - Pay 100,000€ fixed cost
- ◆ Profit $\pi = 150 \cdot \min\{D, Q\} - 100 \cdot Q - 100,000$
- ◆ IDEA decides what Q between 4,000 and 10,000 to order

OPS Analytics MOOC, Week 4 Advanced Session

4

An algebraic formulation of the optimization problem

- ◆ We want to find the optimal order quantity: decision variable Q
- ◆ So we simulate. Suppose we generate 10 samples of demand
 - Call the i^{th} sample D_i ... where $i=1,2,\dots,10$
- ◆ If we order Q and the demand sample was D_i
 - Then profit was $\pi_i = 150 * \min\{D_i, Q\} - 100 * Q - 100,000$
- ◆ We then average the profits over all 10 samples
 - Average $\pi_{average} = 1/10 [\pi_1 + \pi_2 + \dots + \pi_{10}]$
- ◆ We maximize
 - $\max \pi_{average}$
 - subject to
 - $\pi_i = 150 * \min\{D_i, Q\} - 100 * Q - 100,000$ (for $i=1,\dots,10$)
 - $\pi_{average} = 1/10 [\pi_1 + \pi_2 + \dots + \pi_{10}]$
 - $4,000 \leq Q \leq 10,000$

OPS Analytics MOOC, Week 4 Advanced Session

5

For sales $S_i = \min\{D_i, Q\}$ there's a kink when D_i equals Q

OPS Analytics MOOC, Week 4 Advanced Session

6

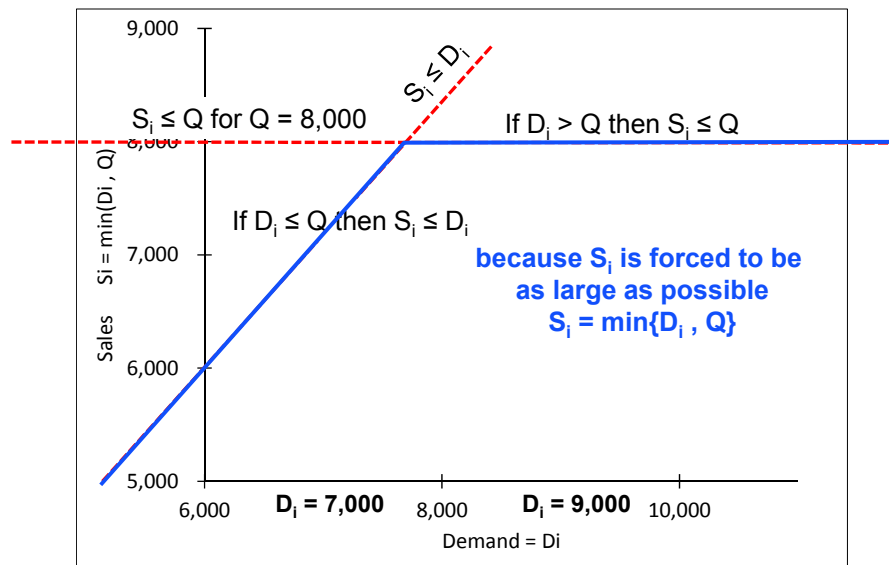

We can avoid this bad type of non-linearity

- ◆ Original formulation $\max \pi_{\text{average}}$
 subject to
 $\pi_{\text{average}} = 1/10 [\pi_1 + \pi_2 + \dots + \pi_{10}]$
 $\pi_i = 150 * \min\{D_i, Q\} - 100 * Q - 100,000 \quad (\text{for } i=1, \dots, 10)$
 $4,000 \leq Q \leq 10,000$
- ◆ We'll add 10 decision variables, one for each sample
 - Let S_i be the number of units sold in sample i
 - Now we let have $\pi_i = 150 * S_i - 100 * Q - 100,000 \quad (\text{for } i=1, \dots, 10)$
- ◆ We'll eliminate the 'min's and use two constraints to define each S_i
 - $S_i \leq D_i \quad (\text{for } i=1, \dots, 10)$
 - $S_i \leq Q \quad (\text{for } i=1, \dots, 10)$
- ◆ The constraints work because the optimization maximizes each S_i

OPS Analytics MOOC, Week 4 Advanced Session

7

The two constraints are evaluated for a given D_i and Q

OPS Analytics MOOC, Week 4 Advanced Session

8

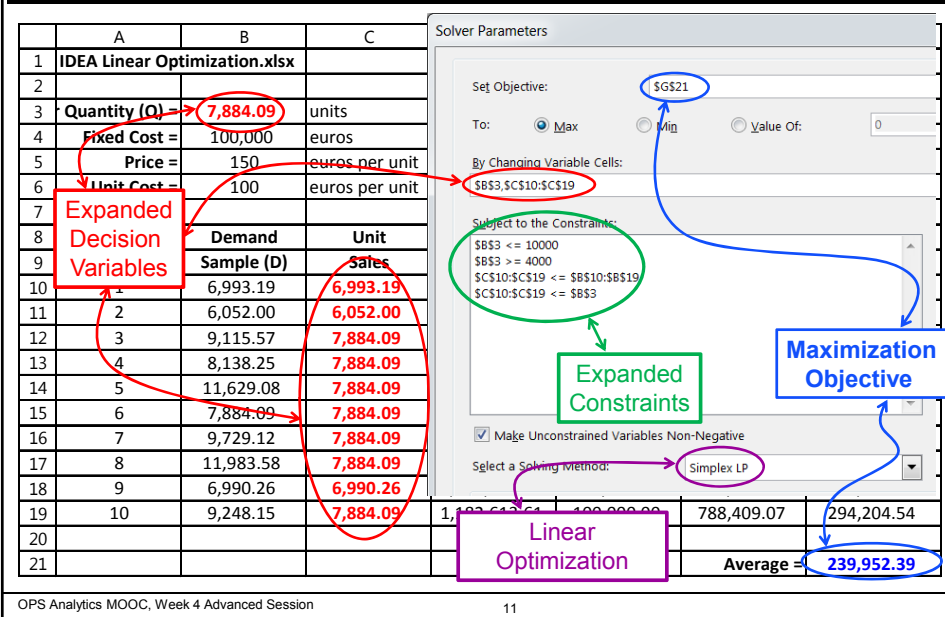

The full linear formulation

- ◆ Original formulation $\max \pi_{\text{average}}$
 subject to
 $\pi_{\text{average}} = 1/10 [\pi_1 + \pi_2 + \dots + \pi_{10}]$
 $\pi_i = 150 * \min\{D_i, Q\} - 100 * Q - 100,000$ (for $i=1, \dots, 10$)
 $Q \geq 0$
- ◆ Linear formulation $\max \pi_{\text{average}}$
 subject to
 $\pi_{\text{average}} = 1/10 [\pi_1 + \pi_2 + \dots + \pi_{10}]$
 $\pi_i = 150 * \min\{D_i, Q\} - 100 * Q - 100,000$ (for $i=1, \dots, 10$)
 $S_i \leq D_i$ (for $i=1, \dots, 10$)
 $S_i \leq Q$ (for $i=1, \dots, 10$)
 $Q \geq 0$

21				$=\text{AVERAGE}(G10:G19)$		Average =	(1,100,000.00)

Optimized version of linear spreadsheet example

Wrap-up for Week 4 Advanced Session 2

- ◆ The $\min(D_i, Q)$ in our newsvendor formulation was not linear
 - It had a "kink" at $D_i = Q$
- ◆ We added extra decision variables and constraints to work around it
 - Decision variables S_i were the unit sales for each sample $i = 1, \dots, 10$
 - Constraints $S_i \leq D_i$ so sales would never be more than demand
 - Constraints $S_i \leq Q$ so sales would never be more than the order quantity
- ◆ When solver maximizes average profits, each S_i is maximized
 - Even though it would be feasible for an $S_i < D_i$ and $S_i < Q$
 - Maximization forces the S_i to grow until it hits one or the other constraint
- ◆ So the problem behaves as if $S_i = \min(D_i, Q)$
